### Methamphetamine Fast Facts

- Methamphetamine is usually a white, bitter-tasting powder or a pill. Crystal methamphetamine looks like glass fragments or shiny, bluish-white rocks.

- Methamphetamine is a stimulant drug that is chemically similar to amphetamine (a drug used to treat ADHD and narcolepsy).

- People can take methamphetamine by smoking, swallowing, snorting, or injecting the drug.

- Methamphetamine increases the amount of dopamine in the brain, which is involved in movement, motivation, and reinforcement of rewarding behaviors.

- Short-term health effects include increased wakefulness and physical activity, decreased appetite, and increased blood pressure and body temperature.

- Long-term health effects include risk of addiction; risk of contracting HIV and hepatitis; severe dental problems; intense itching, leading to skin sores from scratching; violent behavior; and paranoia.

- Methamphetamine can be highly addictive. When people stop taking it, withdrawal symptoms can include anxiety, fatigue, severe depression, psychosis, and intense drug cravings.

- A person can overdose on methamphetamine. Because methamphetamine overdose often leads to a stroke, heart attack, or organ problems, first responders and ER doctors try to treat the overdose by treating these conditions.

- The most effective treatments for methamphetamine addiction currently are behavioral therapies. There are currently no government-approved medications to treat methamphetamine addiction.

*With the right treatment plan, recovery is possible.*
